

ON A QUADRATIC ESTIMATE RELATED TO THE KATO CONJECTURE AND BOUNDARY VALUE PROBLEMS

PASCAL AUSCHER, ANDREAS AXELSSON, AND ALAN McINTOSH

ABSTRACT. We provide a direct proof of a quadratic estimate that plays a central role in the determination of domains of square roots of elliptic operators and, as shown more recently, in some boundary value problems with L^2 boundary data. We develop the application to the Kato conjecture and to a Neumann problem. This quadratic estimate enjoys some equivalent forms in various settings. This gives new results in the functional calculus of Dirac type operators on forms.

1. INTRODUCTION

The goal of this paper is first to present a self-contained and simple proof of the following quadratic estimate, and second, to convince the reader that this is a central estimate in this area.

Theorem 1.1. *Let n, m be positive integers, $\mathcal{H} = L^2(\mathbf{R}^n, \mathbf{C}^m)$ and D, B be operators on $\mathcal{H}$ satisfying the requirements (H). Then one has the quadratic estimate*

$$(1) \quad \int_0^\infty \|t^k BD(I + t^{2k} BDBD)^{-1}u\|^2 \frac{dt}{t} \lesssim \|u\|^2, \quad \text{for all } u \in \mathcal{H}.$$

One uses $(\cdot, \cdot)$ and $\|\cdot\|$ for the hermitian product and norm on $\mathcal{H}$. The hypotheses (H) consist of the following set of requirements.

- (H1) The operator $D : \mathcal{D}(D) \longrightarrow \mathcal{H}$ is a homogeneous k th order differential operator with constant coefficients.
- (H2) D is self-adjoint.
- (H3) D is strictly accretive on its range, i.e.

$$\|\nabla^k u\| \lesssim \|Du\|, \quad \text{for all } u \in \mathcal{D}(D) \cap \overline{\mathcal{R}(D)}.$$

- (H4) B is a bounded operator on $\mathcal{H}$.

- (H5) B is strictly accretive on $\mathcal{R}(D)$: there is a constant $\delta > 0$ such that

$$\operatorname{Re}(BDu, Du) \geq \delta \|Du\|^2, \quad \text{for all } u \in \mathcal{D}(D).$$

- (H6) (Off-diagonal decay) For every integer N there exists $C_N > 0$ such that

$$(2) \quad \|t^k BD(I + t^{2k} BDBD)^{-1}u\|_{L^2(E)} \leq C_N \langle \operatorname{dist}(E, F)/t \rangle^{-N} \|u\|$$

for all $t > 0$, whenever $E, F \subset \mathbf{R}^n$ are closed sets, $u \in \mathcal{H}$ satisfies $\operatorname{supp} u \subset F$.

We have set $\langle x \rangle := 1 + |x|$, and $\operatorname{dist}(E, F) := \inf\{|x - y| : x \in E, y \in F\}$.

In this paper, if A is a (densely defined) unbounded linear operator on $\mathcal{H}$ then $\mathcal{D}(A)$, $\mathcal{N}(A)$, $\mathcal{R}(A)$ denote respectively, its domain, null space and range. In (H3), $\nabla^k u = (\partial^\alpha u_j)_{|\alpha|=k, 1 \leq j \leq m}$ consists of all the partial derivatives of u of order k . The

assumptions (H2,4,5) imply that BD has spectrum contained in a double sector of the complex plane centered around $\mathbf{R}$ and give boundedness of the operator in (H6) (See Proposition 3.1). The constant in (1) depends on the implicit constants in (H).

We mention right away that our interest is in operators B of multiplication by $B(x)$, identified as a matrix having coefficients in $L^\infty(\mathbf{R}^n, \mathbf{C})$, in which case (H5) is a form of Gårding inequality. When D is first order, i.e. $k = 1$, and B is such a multiplication operator, then the off-diagonal decay (H6) holds true. Moreover, when $k > 1$, then (H6) is still satisfied in the case of most interest to us. (See Section 5.) However, we wanted to enlighten the observation that only (H6) is needed (in our arguments). We also stress that D is not assumed to be one-to-one.

This theorem is proved in [8] for first order D , i.e. $k = 1$, as a corollary of another quadratic estimate. Our direct proof is shorter and simpler from the algebraic point of view, and also from the analysis point of view even though the same deep ideas are involved (Carleson measures, $T(b)$ argument). Furthermore, our proof allows a simultaneous treatment of higher order D , i.e. $k \geq 2$, which is new.

The interest of proving a quadratic estimate is mainly in the following proposition as a corollary of results developed in [22].

Proposition 1.2. *Assume that B, D satisfy (H2,4,5) on a Hilbert space $\mathcal{H}$, that BD satisfies the quadratic estimate (1), and that B^*D satisfies the same quadratic estimate with B^* in place of B . Then the operator $\operatorname{sgn}(BD)$ is bounded on $\mathcal{H}$ and invertible on $\overline{R(BD)}$.*

The operator $\operatorname{sgn}(BD)$ is zero on $\mathbf{N}(BD)$ and satisfies $(BDBD)^{1/2} = \operatorname{sgn}(BD)BD$ on $\mathbf{D}(D)$. More is true, in particular BD has a bounded holomorphic functional calculus on $\mathcal{H}$. We remark that the specific nature of $\mathcal{H}$, B and D is not used in this proposition, which follows from operator theoretic considerations, once quadratic estimates for the operators BD and B^*D have been proved.

When $k = 1$, we obtain the following corollary to this result, once we have proved Proposition 5.1. Note that if B satisfies (H4,5), then so does B^* .

Corollary 1.3. *Assume that B, D satisfy (H1-5) on $L^2(\mathbf{R}^n, \mathbf{C}^m)$, that $k = 1$, and that B is multiplication by a function $B \in \underline{L^\infty(\mathbf{R}^n, \mathcal{L}(\mathbf{C}^m))}$. Then the operator $\operatorname{sgn}(BD)$ is bounded on $\mathcal{H}$ and invertible on $\overline{R(BD)}$.*

When $k > 1$, we do not know if B being a multiplication operator is enough, in addition to (H1-5), to conclude for the boundedness of $\operatorname{sgn}(BD)$. It is the case when B, D are as in Section 2.1 and the boundedness of $\operatorname{sgn}(BD)$ appears new.

Known consequences of the boundedness of operators $\operatorname{sgn}(BD)$ are short proofs of the Kato conjecture for elliptic systems in divergence form [4, 5] and the boundedness of the Cauchy integral on Lipschitz curves [13] (see Section 2). In Section 8 we give a pedestrian account of one of the results obtained in [3] concerning boundary value problems for second order elliptic systems which, in particular, give new proofs of solvability for single equations with real symmetric coefficients established in [19, 15, 20]. In Section 10, we show that the quadratic estimate for BD has different equivalent formulations with operators built by functional analytic considerations, including the one studied in [8], and we present a new application related to BVPs for differential forms.

The quadratic estimate (1) has some further interest. It is easily seen to be stable under perturbation with lower order terms. This implies a simple proof of

the Kato conjecture for inhomogeneous elliptic operators (or systems) in divergence form, where previously it required an interpolation procedure from pure operators or a longer argument [6] (See also [9]). The extension to inhomogeneous situations is motivated also by potential applicability to time-harmonic Maxwell's equations. See the introduction of [3].

Acknowledgments.

This work grew out from a visit of the last two named authors to the Université Paris-Sud. A.A. and A.Mc. thank this University for partial support. This research was also supported by the Australian Government through the Australian Research Council and through the International Science Linkages FAST program.

Thanks are also due to the organisers of the El Escorial 2008 conference for opportunity of presenting this work both in lectures and in these proceedings, and for a well organised and stimulating conference. We also thank the anonymous referee for suggestions that improved the presentation of this article.

2. KATO AND CAUCHY

We present two typical applications of the boundedness of $\text{sgn}(BD)$ already in the literature (at least when $k = 1$). We refer to [8] and the references therein for a number of further applications.

2.1. Kato. The application to the square root of elliptic systems $L = (\nabla^k)^* A \nabla^k$ is as follows: A is multiplication by a bounded matrix $A(x)$, and one assumes the Gårding inequality

$$\text{Re}(A \nabla^k u, \nabla^k u) \geq \delta \|\nabla^k u\|^2, \quad \text{for all } u \in H^k(\mathbf{R}^n, \mathbf{C}^N).$$

Here u is $\mathbf{C}^N$ -valued. Thus, we set $L^2(\mathbf{R}^n, \mathbf{C}^m) = L^2(\mathbf{R}^n, \mathbf{C}^N) \oplus L^2(\mathbf{R}^n, \mathbf{C}^{Np})$ where $m = N + Np$ and p is the length of the array ∇^k ,

$$(3) \quad D := \begin{bmatrix} 0 & (\nabla^k)^* \\ \nabla^k & 0 \end{bmatrix}, \quad B := \begin{bmatrix} I & 0 \\ 0 & A \end{bmatrix}.$$

One easily checks (H1-5). For (H6), see Section 5. If $M = A(\nabla^k)(\nabla^k)^*$, then

$$(BD)^2 = \begin{bmatrix} L & 0 \\ 0 & M \end{bmatrix}, \quad \sqrt{(BD)^2} = \begin{bmatrix} \sqrt{L} & 0 \\ 0 & \sqrt{M} \end{bmatrix}.$$

Since $\sqrt{(BD)^2} = \text{sgn}(BD)BD$, we get for $u \in L^2(\mathbf{R}^n, \mathbf{C}^N)$ under appropriate domain assumptions that,

$$\|\sqrt{L}u\| = \left\| \sqrt{(BD)^2} \begin{bmatrix} u \\ 0 \end{bmatrix} \right\| \approx \left\| BD \begin{bmatrix} u \\ 0 \end{bmatrix} \right\| = \|A(\nabla^k u)\| \approx \|\nabla^k u\|.$$

2.2. Cauchy. As for the Cauchy integral, assume $n = m = 1$, $D = -i\frac{d}{dx}$ and B is multiplication by $b(x) = \frac{1}{a(x)}$ where $a \in L^\infty(\mathbf{R}, \mathbf{C})$ with $\text{Re } a \geq \delta > 0$. Then $\text{sgn}(BD)$ is similar to the Cauchy integral on the Lipschitz curve with parametrization $z(x)$ defined by $z'(x) = a(x)$.

3. PROOF OF THE MAIN THEOREM

3.1. Functional calculus for BD . First we need some review on functional calculus. Because of (H2), D is closed and densely defined and there is an orthogonal splitting

$$(4) \quad \mathcal{H} = \mathbf{N}(D) \oplus \overline{\mathbf{R}(D)}.$$

Define closed double sectors in the complex plane by

$$S_\omega := \{z \in \mathbf{C} : |\pm \arg z| \leq \omega \cup \{0\}\},$$

and define the *angle of accretivity* of B to be

$$\omega := \sup_{v \neq 0} |\arg(Bv, v)| < \pi/2.$$

Proposition 3.1. *Under (H2,4,5), we have*

- (i) *The operator BD is ω -bisectorial, i.e. $\sigma(BD) \subset S_\omega$ and there are resolvent bounds $\|(\lambda I - BD)^{-1}\| \lesssim 1/\text{dist}(\lambda, S_\omega)$ when $\lambda \notin S_\omega$.*
- (ii) *The operator BD has range $\mathbf{R}(BD) = B\mathbf{R}(D)$ and null space $\mathbf{N}(BD) = \mathbf{N}(D)$ such that topologically (but in general non-orthogonally) one has*

$$\mathcal{H} = \overline{\mathbf{R}(BD)} \oplus \mathbf{N}(BD).$$

- (iii) *The restriction of BD to $\overline{\mathbf{R}(BD)}$ is a closed and injective operator with dense range in $\overline{\mathbf{R}(BD)}$, with estimates on spectrum and resolvents as in (i).*

These properties of closed operators of the form BD have been known for some time in the case when D is one-one, see for example [1]. When D is not one-one, first prove (ii), using (4) and (H5), and then adapt the proof in [1] to prove (iii). Part (i) follows. Note that this proposition only uses the fact that D is self-adjoint and B bounded and strictly accretive on $\mathbf{R}(D)$.

We set $R_s^B = (I + isBD)^{-1}$ for $s \in \mathbf{R}$. Then

$$Q_t^B = \frac{1}{2i}(R_{-t^k}^B - R_{t^k}^B) = t^k BD(1 + t^{2k} BDBD)^{-1}$$

and also $\frac{1}{2}(R_{-t^k}^B + R_{t^k}^B) = (1 + t^{2k} BDBD)^{-1}$. It follows from the previous result that R_s^B , hence Q_t^B and $(1 + t^{2k} BDBD)^{-1}$, are uniformly bounded operators on $\mathcal{H}$.

We now come to the proof of Theorem 1.1 and assume all the requirements in (H).

3.2. Reduction to a Carleson measure. Observe that by item (ii) of Proposition 3.1, as Q_t^B vanishes on $\mathbf{N}(BD)$ it is enough to prove the quadratic estimate (1) for $u \in \overline{\mathbf{R}(BD)}$, hence for $u \in \mathbf{R}(BD)$. Setting $\Theta_t = Q_t^B B$, it amounts to showing $\int_0^\infty \|\Theta_t Dv\|^2 \frac{dt}{t} \lesssim \|Dv\|^2$ for all $v \in \mathbf{D}(D)$.

Let P_t be a nice approximation of the identity, i.e. the convolution with a real valued function $t^{-n}\varphi(x/t)$ with φ smooth and having Fourier transform identically 1 near 0. Let P_t act on $\mathbf{C}^m$ -valued function componentwise.

Proposition 3.2.

$$(5) \quad \int_0^\infty \|\Theta_t(I - P_t)Dv\|^2 \frac{dt}{t} \lesssim \|Dv\|^2, \quad v \in \mathbf{D}(D).$$

Proof. For the purpose of this proof, by using the splitting (4), one can even assume $v \in \overline{\mathbf{R}(D)}$. Since P_t and D commute and $(I - P_t)v \in \mathbf{D}(D)$, we have

$$\Theta_t(I - P_t)Dv = (\Theta_t D)(I - P_t)v = t^k(BD)^2(I + (t^k BD)^2)^{-1}(I - P_t)v.$$

Now $(t^k BD)^2(I + (t^k BD)^2)^{-1} = I - (I + (t^k BD)^2)^{-1}$ is uniformly bounded, hence

$$\|\Theta_t(I - P_t)Dv\| \lesssim \frac{1}{t^k} \|(I - P_t)v\|.$$

Standard Fourier arguments show that

$$\int_0^\infty \|(I - P_t)v\|^2 \frac{dt}{t^{2k+1}} \lesssim \|\nabla^k v\|^2$$

and we conclude the proof of (5) using (H3). $\square$

Remark 3.3. There are different possible choices of P_t 's. For example, following [8] one can take $P_t = (I + t^{2k} D^2)^{-1}$. The organisation of the reduction to a Carleson measure would be somewhat different.

Next, we perform the principal part approximation.

We use the following dyadic decomposition of $\mathbf{R}^n$. Let $\Delta = \bigcup_{j=-\infty}^\infty \Delta_{2^j}$ where $\Delta_{2^j} := \{2^j(k + (0, 1]^n) : k \in \mathbf{Z}^n\}$. For a dyadic cube $Q \in \Delta_{2^j}$, denote by $l(Q) = 2^j$ its *sidelength*, by $|Q| = 2^{nj}$ its *volume*. We set $\Delta_t = \Delta_{2^j}$ if $2^{j-1} < t \leq 2^j$. Let the *dyadic averaging operator* $S_t : \mathcal{H} \rightarrow \mathcal{H}$ be given by

$$S_t u(x) := u_Q := \fint_Q u(y) dy = \frac{1}{|Q|} \int_Q u(y) dy$$

for every $x \in \mathbf{R}^n$ and $t > 0$, where Q is the unique dyadic cube in Δ_t that contains x . We remark that $S_t^2 = S_t$.

Definition 3.4. By the *principal part* of $(\Theta_t)_{t>0}$ we mean the multiplication operators γ_t defined by

$$\gamma_t(x)w := (\Theta_t w)(x)$$

for every $w \in \mathbf{C}^m$. We view w on the right-hand side of the above equation as the constant function valued in $\mathbf{C}^m$ defined on $\mathbf{R}^n$ by $w(x) := w$. We identify $\gamma_t(x)$ with the (possibly unbounded) multiplication operator $\gamma_t : f(x) \mapsto \gamma_t(x)f(x)$.

Lemma 3.5. *The operator Θ_t extends to a bounded operator from L^∞ into L_{loc}^2 . In particular we have well defined functions $\gamma_t \in L_{loc}^2(\mathbf{R}^n; \mathcal{L}(\mathbf{C}^m, \mathbf{C}^m))$ with bounds*

$$\fint_Q |\gamma_t(y)|^2 dy \lesssim 1$$

for all $Q \in \Delta_t$. Moreover, $\|\gamma_t S_t\| \lesssim 1$ uniformly for all $t > 0$.

Proof. Fix a cube $Q \in \Delta_t$ and $f \in L^\infty(\mathbf{R}^n, \mathbf{C}^m)$ with $\|f\|_\infty = 1$. Then write $f = f_0 + f_1 + f_2 + \dots$ where $f_0 = f$ on $2Q$ and 0 elsewhere and if $j \geq 1$, $f_j = f$ on $2^{j+1}Q \setminus 2^jQ$ and 0 elsewhere. Then apply Θ_t and use (H6) for each term $\Theta_t f_j$ with N large enough and sum to obtain

$$\fint_Q |(\Theta_t f)(y)|^2 dy \leq C.$$

If we do this for the constant functions with values describing an orthonormal basis of $\mathbf{C}^m$ and sum, we obtain an upper bound for the desired average of γ_t . Next, for a function $f \in \mathcal{H}$,

$$\|\gamma_t S_t f\|^2 = \sum_{Q \in \Delta_t} \int_Q \left| \gamma_t(y) \left(\int_Q f \right) \right|^2 dy \lesssim \sum_{Q \in \Delta_t} |Q| \left| \int_Q f \right|^2 \leq \|f\|^2.$$

□

We have the following principal part approximation of Θ_t by $\gamma_t S_t$.

Lemma 3.6. *We have*

$$(6) \quad \int_0^\infty \|\Theta_t P_t f - \gamma_t S_t f\|^2 \frac{dt}{t} \lesssim \|f\|^2, \quad f \in \mathcal{H}.$$

Combining this with Proposition 3.2, we obtain the principal part approximation

$$(7) \quad \int_0^\infty \|\Theta_t Dv - \gamma_t S_t Dv\|^2 \frac{dt}{t} \lesssim \|Dv\|^2, \quad v \in D(D).$$

Proof. Write

$$\Theta_t P_t - \gamma_t S_t = (\Theta_t P_t - \gamma_t S_t P_t) + (\gamma_t S_t (P_t - S_t)) + (\gamma_t S_t^2 - \gamma_t S_t).$$

Because $S_t^2 = S_t$, the last term vanishes. Next, as $\gamma_t S_t$ is uniformly bounded as an operator on $\mathcal{H}$, we have

$$\int_0^\infty \|\gamma_t S_t (P_t - S_t) f\|^2 \frac{dt}{t} \lesssim \int_0^\infty \|(P_t - S_t) f\|^2 \frac{dt}{t} \lesssim \|f\|^2.$$

The last inequality is done componentwise and is classical (See, e.g. [6], p. 172).

We pass to the first term. We remark that for $t > 0$ fixed and $x \in \mathbf{R}^n$, then

$$(\Theta_t P_t - \gamma_t S_t P_t) f(x) = \Theta_t \left(g - \int_Q g \right)(x)$$

where $g = P_t f$ and Q is the only dyadic cube in Δ_t containing x . Define $C_0(Q) = 2Q$ and $C_j(Q) = 2^{j+1}Q \setminus 2^jQ$ if $j \in \mathbf{N}^*$. Then

$$\begin{aligned}
\|(\Theta_t P_t - \gamma_t S_t P_t)f\|^2 &= \sum_{Q \in \Delta_t} \int_Q \left| \Theta_t \left(g - \int_Q g \right) \right|^2 \\
&\leq \sum_{Q \in \Delta_t} \left(\sum_{j \geq 0} \left(\int_Q \left| \Theta_t \left(\mathbf{1}_{C_j(Q)} \left(g - \int_Q g \right) \right) \right|^2 \right)^{1/2} \right)^2 \\
&\lesssim \sum_{Q \in \Delta_t} \left(\sum_{j \geq 0} 2^{-jN} \left(\int_{C_j(Q)} \left| g - \int_Q g \right|^2 \right)^{1/2} \right)^2 \\
&\lesssim \sum_{Q \in \Delta_t} \sum_{j \geq 0} 2^{-jN} \int_{C_j(Q)} \left| g - \int_Q g \right|^2 \\
&\lesssim \sum_{Q \in \Delta_t} \sum_{j \geq 0} 2^{-jN} 2^{2j} \ell(Q)^2 \int_{2^{j+1}Q} |\nabla g|^2 \\
&\lesssim t^2 \sum_{j \geq 0} 2^{-jN} 2^{2j} 2^{jn} \int_{\mathbf{R}^n} |\nabla g|^2. \\
&\lesssim t^2 \|\nabla g\|^2.
\end{aligned}$$

We successively used the Minkowski inequality on the second line, (H6) on the third one, Cauchy–Schwarz on the fourth, Poincaré inequality on the fifth, the covering inequality $\sum_{Q \in \Delta_t} \mathbf{1}_{2^{j+1}Q} \lesssim 2^{jn}$ and $\ell(Q) \sim t$ on the sixth and the choice $N > n + 2$ in the last.

Hence

$$\int_0^\infty \|\Theta_t P_t f - \gamma_t S_t P_t f\|^2 \frac{dt}{t} \lesssim \int_0^\infty \|t \nabla P_t f\|^2 \frac{dt}{t} \lesssim \|f\|^2$$

using the standard Littlewood-Paley inequality on each component of f . $\square$

Before we state the conclusion of this reduction, there is an essential observation. Identifying constant functions with their values, observe that Dv takes values in the vector space

$$\mathcal{D} = \{DL : L : \mathbf{R}^n \rightarrow \mathbf{C}^m, L \text{ a polynomial of degree } k\} \subset \mathbf{C}^m$$

and so does $S_t(Dv)$. Therefore, one considers the restriction of $\gamma_t(x)$ to $\mathcal{D}$. Henceforth, we consider $\gamma_t(x)$ as an element of $\mathcal{L}(\mathcal{D}, \mathbf{C}^m)$ and its norm $|\gamma_t(x)|$ is measured in this space.

Recall that $\mathbf{R}_+^{n+1} \rightarrow \mathcal{L}(\mathcal{D}, \mathbf{C}^m), (x, t) \mapsto \gamma_t(x)$, is a *dyadic Carleson function* if there exists $C < \infty$ such that

$$\iint_{R(Q)} |\gamma_t(x)|^2 \frac{dx dt}{t} \leq C^2 |Q|$$

for all dyadic cubes $Q \subset \mathbf{R}^n$. Here $R(Q) := Q \times (0, \ell(Q)]$ is the Carleson box over Q . We define the dyadic Carleson norm $\|\gamma_t\|_C$ to be the smallest constant C . The form of Carleson's lemma that we need and applied componentwise is as follows (see [6], p.168 and references therein).

Proposition 3.7.

$$\int_0^\infty \|\gamma_t S_t Dv\|^2 \frac{dt}{t} \lesssim \|\gamma_t\|_C^2 \|Dv\|^2, \quad v \in D(D).$$

Therefore, we have obtained

Proposition 3.8. *If the restriction of $\gamma_t(x)$ to $\mathcal{D}$ is a dyadic Carleson function then the conclusion of Theorem 1.1 holds.*

Remark 3.9. At this point, it is nowadays understood that the Carleson measure estimate can be achieved by what is called a $T(b)$ argument, which consists in finding suitable test functions adapted to the operator $\Theta_t = Q_t B$. However, a dichotomy appears on remarking that we can prove (7) for functions of the form $f = Dv \in \overline{\mathbf{R}(D)}$, but not for functions $f \in \mathbf{N}(D)$. This comes from the use of (H3) in Proposition 3.2. The simple situation is when D is one-one (or, equivalently, D has dense range by (4)): the test functions are simply the columns of B^{-1} . When D fails to be one-one, this choice does not work as we have to select test functions in the range of D . For the Kato problem, one has one-oneness of the D involved only in one dimension. It is for this reason that the Kato problem was more difficult in dimensions $n \geq 2$ than in one dimension. For a fair comparison, we provide the concluding argument of the proof of Theorem 1.1 in both cases.

3.3. The $\mathbf{T(b)}$ argument when D is injective with dense range. Fix a dyadic cube Q , and let η_Q be a smooth real valued cutoff such that $\eta_Q|_{2Q} = 1$, $\text{supp}(\eta_Q) \subset 3Q$ and $\|\nabla^j \eta_Q\|_\infty \lesssim l^{-j}$ for $j = 1, 2, \dots, k$ with $l = l(Q)$. Denote by B_j^{-1} the j 'th column vector in the matrix B^{-1} , and estimate

$$\begin{aligned} \iint_{R(Q)} |\gamma_t(x)|^2 \frac{dxdt}{t} &\lesssim \iint_{R(Q)} |\gamma_t(x) S_t(\eta_Q B^{-1})|^2 \frac{dxdt}{t} \\ &\lesssim \sum_{j=1}^m \iint_{R(Q)} |\gamma_t(x) S_t(\eta_Q B_j^{-1})|^2 \frac{dxdt}{t} \\ &\lesssim \sum_{j=1}^m \iint_{R(Q)} |\Theta_t(\eta_Q B_j^{-1})|^2 \frac{dxdt}{t} + \sum_{j=1}^m \int_0^\infty \|(\Theta_t - \gamma_t(x) S_t)(\eta_Q B_j^{-1})\|^2 \frac{dt}{t} \\ &\lesssim \sum_{j=1}^m \int_0^{l(Q)} \|(1 + t^{2k}(BD)^2)^{-1} t^k BD(\eta_Q e_j)\|^2 \frac{dt}{t} + \sum_{j=1}^m \|\eta_Q B_j^{-1}\|^2 \\ &\lesssim \sum_{j=1}^m \int_0^{l(Q)} \|D(\eta_Q e_j)\|^2 t^{2k-1} dt + |Q| \lesssim |Q|. \end{aligned}$$

For the first row, we use the fact that B^{-1} is strictly accretive on $\mathcal{H}$, and hence is pointwise uniformly strictly accretive. Here S_t acts componentwise on the matrix. In the first term of row four we write $B\eta_Q B_j^{-1} = \eta_Q B B_j^{-1} = \eta_Q e_j$, where e_j is the j 'th standard basis vector in $\mathbf{C}^m$. To obtain the second term, we apply the principal part approximation (7), using the assumption that the range of D is dense in $\mathcal{H}$ (hence Dv there can be replaced by **any** function in $\mathcal{H}$). In row five we use the uniform boundedness of the operators $(1 + t^{2k}(BD)^2)^{-1}$ and that $D(\eta_Q e_j)$ is supported on $3Q$ and is bounded by l^{-k} .

3.4. The $\mathbf{T(b)}$ argument in the general case. We now consider the general case where D is not an injective operator with dense range in $\mathcal{H}$, so that we need to construct test functions which belong to the range of D . Fix Q a dyadic cube and $w \in \mathcal{D}$ with $|w| = 1$. Let L be a polynomial of degree k such that $w = DL$ and $\sup_{3Q} |\partial^\alpha L(x)| \lesssim l^{k-|\alpha|}$, $0 \leq |\alpha| \leq k-1$ and define $w_Q := D(\eta_Q L)$, where η_Q is the cutoff above. It follows that

$$w_Q \in \mathbf{R}(D), \quad w_Q|_{2Q} = w, \quad \text{supp } w_Q \subset 3Q \quad \text{and} \quad \|w_Q\|_\infty \leq C.$$

Next we define the test function $b_{Q,\epsilon}^w$ for $\epsilon \in (0, 1)$ by

$$b_{Q,\epsilon}^w := Dv_{Q,\epsilon}^w, \quad v_{Q,\epsilon}^w := (I + i(\epsilon l)^k BD)^{-1}(\eta_Q L).$$

Lemma 3.10. *There exists $C > 0$ such that for each $w \in \mathcal{D}$ with $|w| = 1$, each dyadic cube $Q \subset \mathbf{R}^n$ and each $\epsilon \in (0, 1)$,*

$$(8) \quad \int_Q |v_{Q,\epsilon}^w - L|^2 \leq C(\epsilon l)^{2k} |Q|,$$

$$(9) \quad \int_Q |b_{Q,\epsilon}^w - w|^2 \leq C|Q|,$$

$$(10) \quad \left| \int_Q b_{Q,\epsilon}^w - w \right| \leq C\sqrt{\epsilon},$$

$$(11) \quad \iint_{R(Q)} |\gamma_t(x) S_t b_{Q,\epsilon}^w(x)|^2 \frac{dx dt}{t} \leq C\epsilon^{-2k} |Q|.$$

Proof. Using $(I + isBD)^{-1} - I = -isBD(I + isBD)^{-1}$ and $\eta_Q L \in \mathbf{D}(BD)$, we have

$$v_{Q,\epsilon}^w - \eta_Q L = -i(\epsilon l)^k (I + i(\epsilon l)^k BD)^{-1}(Bw_Q).$$

The properties of w_Q and η_Q and the boundedness of $(I + isBD)^{-1}B$ imply (8). Applying D we get,

$$b_{Q,\epsilon}^w - w_Q = -i(\epsilon l)^k D(I + i(\epsilon l)^k BD)^{-1}(Bw_Q).$$

The properties of w_Q and the boundedness of $sD(I + isBD)^{-1}B$ imply (9).

Next, let $\varphi: \mathbf{R}^n \rightarrow [0, 1]$ be a smooth function which is 1 on $(1-t)Q$, 0 on Q^c with $\|\nabla^k \varphi\|_\infty \leq C(tl)^{-k}$ with $t \in (0, 1)$ to be chosen. We can write

$$\int_Q b_{Q,\epsilon}^w - w = \int_Q \varphi D(v_{Q,\epsilon}^w - L) + \int_Q (1 - \varphi)(b_{Q,\epsilon}^w - w) = I + II.$$

Using (9) and the properties of φ together with Cauchy-Schwarz inequality, we obtain

$$|II| \leq C\sqrt{t}.$$

For I , we can write using the properties φ and integration by parts,

$$\int_Q \varphi D(v_{Q,\epsilon}^w - L) = \int_{\mathbf{R}^n} \varphi D(v_{Q,\epsilon}^w - \eta_Q L) = \int_{\mathbf{R}^n} (\tilde{D}\varphi)(v_{Q,\epsilon}^w - \eta_Q L) = \int_Q (\tilde{D}\varphi)(v_{Q,\epsilon}^w - L)$$

where $\tilde{D}\varphi$ is some $\mathcal{L}(\mathbf{C}^m, \mathbf{C}^m)$ -valued function bounded by $C\|\nabla^k \varphi\|_\infty$ and supported in $Q \setminus (1-t)Q$, so that we obtain

$$|I| \leq C\epsilon^k / t^{k-1/2}.$$

Hence, choosing $t = \epsilon$, we have shown (10).

Eventually, to prove (11), we can use the principal part approximation in Lemma 3.6 (backwards) because $b_{Q,\epsilon}^w = Dv_{Q,\epsilon}^w$ and $\|b_{Q,\epsilon}^w\| \lesssim 1$ and it suffices to establish

$$(12) \quad \iint_{R(Q)} |\Theta_t b_{Q,\epsilon}^w(x)|^2 \frac{dxdt}{t} \leq C\epsilon^{-2k}|Q|.$$

Now,

$$\begin{aligned} \Theta_t b_{Q,\epsilon}^w &= t^k BD(I + t^{2k} BDBD)^{-1} BD(I + i(\epsilon l)^k BD)^{-1} (\eta_Q L) \\ &= t^k BD(I + t^{2k} BDBD)^{-1} (I + i(\epsilon l)^k BD)^{-1} (Bw_Q). \\ &= (t/\epsilon l)^k (I + t^{2k} BDBD)^{-1} (\epsilon l)^k BD(I + i(\epsilon l)^k BD)^{-1} (Bw_Q) \end{aligned}$$

Since $(I + t^{2k} BDBD)^{-1}$ and $(\epsilon l)^k BD(I + i(\epsilon l)^k BD)^{-1}$ are bounded uniformly with respect to t and ϵl , we have

$$\|\Theta_t b_{Q,\epsilon}^w\| \leq C(t/\epsilon l)^k.$$

Integrating over $t \in (0, l]$ we obtain (12). $\square$

We now perform a sectorial decomposition and then a stopping-time argument to estimate the dyadic Carleson norm on $\gamma_t(x)$. Cover $\mathcal{L}(\mathcal{D}, \mathbf{C}^m)$ by a finite number of sectors $\mathcal{C}_{\gamma,\nu} = \{\kappa \in \mathcal{L}(\mathcal{D}, \mathbf{C}^m); |\kappa - |\kappa|\gamma| \leq \nu|\kappa|\}$, with $\gamma \in \mathcal{L}(\mathcal{D}, \mathbf{C}^m)$, $|\gamma| = 1$, and $\nu \in (0, 1)$. The number ν is to be chosen later. Fix such a sector. It is enough to estimate the Carleson norm of

$$\tilde{\gamma}_t(x) = \mathbf{1}_{\gamma_t(x) \in \mathcal{C}_{\gamma,\nu}} \gamma_t(x).$$

Pick $w \in \mathcal{D}$, $w^* \in \mathbf{C}^m$ such that $(\gamma w, w^*) = 1$ and $|w| = |w^*| = 1$. For any $\kappa \in \mathcal{C}_{\gamma,\nu}$, we have

$$\operatorname{Re} [|\kappa|(\gamma w, w^*) - (\kappa w, w^*)] \leq \nu|\kappa|$$

thus

$$(1 - \nu)|\kappa| \leq \operatorname{Re}(\kappa w, w^*).$$

Fix a cube Q . Applying this to $\tilde{\gamma}_t(x)$ with $(x, t) \in R(Q)$, we obtain

$$\begin{aligned} (1 - \nu)|\tilde{\gamma}_t(x)| &\leq \operatorname{Re}(\tilde{\gamma}_t(x)w, w^*) \\ &\leq \operatorname{Re}(\tilde{\gamma}_t(x)S_t b_{Q,\epsilon}^w(x), w^*) + |\tilde{\gamma}_t(x)| \operatorname{Re}(\gamma(w - S_t b_{Q,\epsilon}^w(x)), w^*) \\ &\quad + \operatorname{Re}((\tilde{\gamma}_t(x) - |\tilde{\gamma}_t(x)|\gamma)(w - S_t b_{Q,\epsilon}^w(x)), w^*) \\ &\leq |\gamma_t(x)S_t b_{Q,\epsilon}^w(x)| + |\tilde{\gamma}_t(x)| \operatorname{Re}(\gamma(w - S_t b_{Q,\epsilon}^w(x)), w^*) \\ &\quad + \nu|\tilde{\gamma}_t(x)||w - S_t b_{Q,\epsilon}^w(x)|. \end{aligned}$$

Thus one needs smallness on $\operatorname{Re}(\gamma(w - S_t b_{Q,\epsilon}^w(x)), w^*)$ and a control on the size of $|w - S_t b_{Q,\epsilon}^w(x)|$ on a large portion of $R(Q)$.

Lemma 3.11. *There exists $\epsilon_0 \in (0, 1)$ such that for all $\epsilon \in (0, \epsilon_0)$, any dyadic cube Q contains disjoint dyadic subcubes Q_i with*

$$(13) \quad \sum_i |Q_i| \leq (1 - \epsilon)|Q|,$$

$$(14) \quad \operatorname{Re}(\gamma(w - S_t b_{Q,\epsilon}^w(x)), w^*) \leq 10C\sqrt{\epsilon}, \quad (x, t) \in R(Q) \setminus \cup R(Q_i),$$

$$(15) \quad |w - S_t b_{Q,\epsilon}^w(x)| \leq \sqrt{C/\epsilon}, \quad (x, t) \in R(Q) \setminus \cup R(Q_i).$$

Here, C is the constant appearing in Lemma 3.10.

Assuming this, then we obtain

$$(1 - \nu - 10C\sqrt{\epsilon} - \nu\sqrt{C/\epsilon}) |\tilde{\gamma}_t(x)| \leq |\gamma_t(x) S_t b_{Q,\epsilon}^w(x)|, \quad (x, t) \in R(Q) \setminus \cup R(Q_i).$$

Choosing ϵ and then ν small enough (depending only on C , hence on (H)), we have shown for all Q with the corresponding Q_i

$$(16) \quad |\tilde{\gamma}_t(x)| \leq 2|\gamma_t(x) S_t b_{Q,\epsilon}^w(x)|, \quad (x, t) \in R(Q) \setminus \cup R(Q_i).$$

We finish with a classical observation: fix $\delta > 0$ and

$$A_Q = \sup \frac{1}{|Q'|} \iint_{(x,t) \in R(Q'), t > \delta} |\tilde{\gamma}_t(x)|^2 \frac{dxdt}{t} < \infty$$

where the supremum is taken over all dyadic subcubes of Q . Then, if Q' is such a cube and Q'_i are the subcubes of Q' given by Lemma 3.11

$$\begin{aligned} & \iint_{(x,t) \in R(Q'), t > \delta} |\tilde{\gamma}_t(x)|^2 \frac{dxdt}{t} \\ (17) \quad & \leq 4 \iint_{(x,t) \in R(Q'), t > \delta} |\gamma_t(x) S_t b_{Q',\epsilon}^w(x)|^2 \frac{dxdt}{t} + \sum_i \iint_{(x,t) \in R(Q'_i), t > \delta} |\tilde{\gamma}_t(x)|^2 \frac{dxdt}{t} \\ & \leq 4C\epsilon^{-2k} |Q'| + A_Q \sum_i |Q'_i| \\ & \leq 4C\epsilon^{-2k} |Q'| + A_Q(1 - \epsilon) |Q'|. \end{aligned}$$

Hence, dividing by $|Q'|$ and taking the supremum over Q' we obtain $A_Q \leq 4C\epsilon^{-2k-1}$, and in particular

$$\frac{1}{|Q|} \iint_{(x,t) \in R(Q), t > \delta} |\tilde{\gamma}_t(x)|^2 \frac{dxdt}{t} \leq 4C\epsilon^{-2k-1}.$$

This is independent of $\delta > 0$, hence we obtain the desired estimate by letting δ tend to 0.

It remains to prove Lemma 3.11.

Proof. We fix a dyadic cube Q . We assume ϵ small. Observe that

$$\operatorname{Re}(\gamma \left(w - \oint_Q b_{Q,\epsilon}^w \right), w^*) \leq C\epsilon^{1/2}$$

and

$$\oint_Q |w - b_{Q,\epsilon}^w|^2 \leq C.$$

We subdivide dyadically Q and consider for the subcubes Q' both conditions

$$(18) \quad \operatorname{Re}(\gamma \left(w - \oint_{Q'} b_{Q',\epsilon}^w \right), w^*) > 10C\epsilon^{1/2},$$

$$(19) \quad \oint_{Q'} |w - b_{Q',\epsilon}^w|^2 > C\epsilon^{-1}.$$

If one or the other holds, we stop and put Q' in the sought collection of stopping cubes (Q_i). If none of the conditions hold, we subdivide Q' and iterate the test on subcubes.

We note that $(x, t) \in R(Q) \setminus \cup R(Q_i)$ exactly means that $w - S_t b_{Q,\epsilon}^w(x) = w - f_{Q'} b_{Q,\epsilon}^w$ for a non-stopping cube Q' . Thus (14) and (15) hold immediately.

It remains to show (13). Declare Q_i of type 1 if (18) holds and of type 2 if (19) holds. We let $\Sigma_j = \sum |Q_i|$ where the sum is restricted to cubes of type j . We might count twice cubes of both types but that is not a problem. For cubes of type 2, we have

$$\Sigma_2 \leq \frac{\epsilon}{C} \sum \int_{Q_i} |w - b_{Q,\epsilon}^w|^2 \leq \frac{\epsilon}{C} \int_Q |w - b_{Q,\epsilon}^w|^2 \leq \epsilon |Q|.$$

For cubes of type 1, we have

$$\begin{aligned} 10C\epsilon^{1/2} \Sigma_1 &\leq \sum \operatorname{Re}(\gamma \left(\int_{Q_i} w - b_{Q,\epsilon}^w \right), w^*) \\ &= \operatorname{Re}(\gamma \left(\int_Q w - b_{Q,\epsilon}^w \right), w^*) - \operatorname{Re}(\gamma \left(\int_{Q \setminus \cup Q_i} w - b_{Q,\epsilon}^w \right), w^*). \end{aligned}$$

Using (10) and the Cauchy-Schwarz inequality for the last term, we obtain

$$10C\epsilon^{1/2} X \leq C\epsilon^{1/2} + \sqrt{C}(1 - X)^{1/2}$$

where $X = \Sigma_1/|Q| \in [0, 1]$. The positive root of the corresponding equation is on the order of $1 - 81C\epsilon$ for ϵ small enough. Hence,

$$X \leq 1 - C\epsilon$$

for ϵ small enough. Thus, the total contribution of cubes of both types does not exceed $(1 - C\epsilon + \epsilon)|Q|$, which gives (13) (assuming $C \geq 2$ which we may). $\square$

4. HISTORICAL COMMENTS

The (almost) self-contained proof of Theorem 1.1 follows very closely the strategy of [4] which, of course, builds upon the ideas of many authors, and it also incorporates ideas from the various extensions of this argument found later on. Locating the origin of this and that can be subtle for the reader, so we devote this section to historical comments, giving appropriate credit for the crucial steps based on our understanding. We do not mention less recent progress and refer to [6, 4] for this.

A strategy to solve the Kato conjecture in all dimensions was introduced and developed in [6] under kernel bound assumptions. It first involves the reduction to Carleson measures in such a context - which was named “principal part approximation” in [8] - as described in Section 3.2, exploiting earlier ideas of Coifman-Meyer [14] further elaborated in works of Christ-Journé and Semmes [12, 23]. The present formulation of the principal part approximation is closer to the one in [8]. We have chosen this formulation for the simplicity of its proof (assuming minimal knowledge of Littlewood-Paley-Stein theory). The strategy of [6] required the existence of a set of appropriate test functions in order to prove the Carleson bounds via the “T(b) theorem for square roots”. In [6], Chapter 3 this existence was made an assumption called there “the class (S) assumption”. The construction of such a set was achieved for the first time in [18] to solve the two dimensional Kato problem. Our choice is close to this one, rather than the one used later in [8]. However, we need to exploit the observation made in [2] that one can reduce the action of $\gamma_t(x)$ to a subspace, while this is not necessary in [18] or in [4].

The importance of the inequality (16), or at least an integral version of it, was pointed out in [6], Chapter 3, and found its roots in [23]. The kind of stopping-time argument providing an inequality like (16) leading to (17) is developed for the first time in this context in [18]. It is mentioned in [4] that, in retrospect, this stopping-time argument is akin to an argument of Christ [11] devised for proving a local $T(b)$ theorem for singular integrals. The conical decomposition done in the space of constants ($\mathbf{C}^n$) to estimate the Carleson measure associated to $\gamma_t(x)$ was the main new ingredient of [17]. This provided a means to build a different set of test functions to solve the Kato conjecture in all dimensions under kernel bound assumptions. The removal of such kernel bounds was achieved in [4], thus proving the Kato conjecture for second order operators in full generality. The idea which we use of doing the conical decomposition, not in the space of constants, but within the linear space of matrices to which $\gamma_t(x)$ belongs, is an important observation, made in [5] for proving the Kato conjecture for higher order operators and systems.

Note that our argument is developed on $\mathbf{R}^n$, while the one in [4] was pushed in [9] to Lipschitz domains for mixed boundary value problems. The case of Dirichlet and Neumann boundary conditions had been previously done in [7] by a direct reduction to the $\mathbf{R}^n$ case. It would be of interest to adapt Theorem 1.1 to domains and to obtain new proofs and generalisations of the results just mentioned.

5. VALIDITY OF OFF-DIAGONAL ESTIMATES

Proposition 5.1. *If $k = 1$ then (H6) holds for all B and D with (H1,2,4,5) when also B denotes multiplication by a matrix-valued function $B \in L^\infty(\mathbf{R}^n, \mathcal{L}(\mathbf{C}^m))$. In fact, one even has exponential decay.*

The proof is inspired by the one in [4].

Proof. It is enough to consider $R_t^B = (I + itBD)^{-1}$ for $t \neq 0$, as $Q_t^B = \frac{-1}{2t}(R_t^B - R_{-t}^B)$. Let $d = \text{dist}(E, F)$. We have already proved uniform bounds. So it is enough to prove (2) under the assumption that $|t| \leq \alpha d$ for some constant $\alpha > 0$ to be chosen. Assume $u \in \mathcal{H}$ with $\text{supp } u \subset F$.

Write

$$\tilde{E} := \{x \in \mathbf{R}^n : \text{dist}(x, E) < \frac{1}{2}\text{dist}(x, F)\}$$

and let $\varphi : \mathbf{R}^n \rightarrow [0, 1]$ be a Lipschitz function such that $\text{supp } \varphi \subset \tilde{E}$, $\varphi|_E = 1$ and

$$\|\nabla \varphi\|_\infty \leq 4/d.$$

Let $\eta = e^{\alpha d \varphi/t} - 1$ and observe that $\eta = 0$ on F and $\eta = e^{\alpha d/t} - 1 \geq \frac{1}{2}e^{\alpha d/t}$ on E , thus

$$\frac{1}{2}e^{\alpha d/t} \|R_t^B u\|_{L^2(E)} \leq \|\eta R_t^B u\| \leq \|[\eta I, R_t^B] u\|$$

using that $\eta u = 0$. Next,

$$[\eta I, R_t^B] = it R_t^B [BD, \eta I] R_t^B = it R_t^B B [D, \eta I] R_t^B$$

and $[D, \eta I]$ is multiplication by a function $m e^{\alpha d \varphi/t}$ where m is supported on $\tilde{E}$ with L^∞ norm not exceeding $C \alpha d \|\nabla \varphi\|_\infty / t \leq 4 C \alpha / t$. Thus, using the boundedness of

$R_t^B B$,

$$\begin{aligned} \|\eta R_t^B u\| &\lesssim t \| [D, \eta] R_t^B u \| \\ &\lesssim 4C\alpha \| e^{\alpha d\varphi/t} R_t^B u \| \\ &\lesssim 4C\alpha (\|\eta R_t^B u\| + \|R_t^B u\|). \end{aligned}$$

Hence, choosing α small enough (independent of t, u), gives $\|\eta R_t^B u\| \lesssim \|R_t^B u\| \lesssim \|u\|$ and this proves the proposition. $\square$

Proposition 5.2. *Let $k \geq 2$ and B, D be as in Section 2.1. Then (H6) holds with exponential decay.*

Proof. Observe that

$$Q_t^B \begin{bmatrix} u_1 \\ u_2 \end{bmatrix} = \begin{bmatrix} (I + t^{2k}L)^{-1} (t^k (\nabla^k)^* u_2) \\ t^k A \nabla^k (I + t^{2k}L)^{-1} u_1 \end{bmatrix}.$$

The off-diagonal bounds (2) for $(I + t^{2k}L)^{-1}$ and $t^k \nabla^k (I + t^{2k}L)^{-1}$ have been known for some time: see [16] where it is done for the semi-group $e^{-t^{2k}L}$ instead of the resolvent. However, there is an argument using the spirit of the proof of Proposition 5.1 working directly with Q_t^B instead of R_t . From there the off-diagonal bounds for $(I + t^{2k}L)^{-1} t^k (\nabla^k)^* A$ follow from a duality argument changing A^* to A . We leave details to the reader. $\square$

6. SOME FUNCTIONAL CONSEQUENCES OF THE QUADRATIC ESTIMATE

6.1. Proof of Proposition 1.2. We refer to [1] for details on functional calculus for the class of operators under consideration here. Let us just say that there is a way of defining $\text{sgn}(BD)$ using the following formula

$$(20) \quad \text{sgn}(BD)f = c \int_0^\infty (t^k BD)^3 (1 + t^{2k} BDBD)^{-3} f \frac{dt}{t} = c \int_0^\infty (Q_t^B)^3 f \frac{dt}{t}$$

with $c^{-1} = \int_0^\infty u^{3k-1} (1 + u^{2k})^{-3} du$. This comes from the fact that the function $z \mapsto c \int_0^\infty (t^k z)^3 (1 + t^{2k} z^2)^{-3} \frac{dt}{t}$ is holomorphic on $\mathbf{C} \setminus i\mathbf{R}$ where it coincides with $\text{sgn}(z)$, defined to be 1 on the right half-plane and -1 on the left half-plane, in other words, the holomorphic extension of the sgn function on the real line to $\mathbf{C} \setminus i\mathbf{R}$.

By item (ii), Proposition 3.1, it is enough to define and prove boundedness of $\text{sgn}(BD)$ on $\mathbf{N}(BD)$ and $\overline{\mathbf{R}(BD)}$ separately. For $f \in \mathbf{N}(BD)$ then $Q_t^B f = 0$ for each t , thus $\text{sgn}(BD) = 0$ on $\mathbf{N}(BD)$.

It is easy to see that the integral (20) converges in norm in $\mathcal{H}$ for $f \in \mathbf{D}(BD) \cap \mathbf{R}(BD)$, because then

$$\|(t^k BD)^3 (1 + t^{2k} BDBD)^{-3} f\| \lesssim \min(t^k, t^{-k}).$$

Since $\mathbf{D}(BD) \cap \mathbf{R}(BD)$ is dense in $\overline{\mathbf{R}(BD)}$, this defines $\text{sgn}(BD)$ on the latter provided one shows $\|\text{sgn}(BD)f\| \leq c\|f\|$ for $f \in \mathbf{D}(BD) \cap \mathbf{R}(BD)$.

Let $f \in \mathbf{D}(BD), g \in \mathbf{D}(DB^*)$. Then

$$|((Q_t^B)^3 f, g)| = |(Q_t^B (Q_t^B f), (Q_t^B)^* g)| \lesssim \|Q_t^B f\| \|(Q_t^B)^* g\|$$

and applying the Cauchy-Schwarz inequality

$$|(\text{sgn}(BD)f, g)| \lesssim \left(\int_0^\infty \|Q_t^B f\|^2 \frac{dt}{t} \right)^{1/2} \left(\int_0^\infty \|(Q_t^B)^* g\|^2 \frac{dt}{t} \right)^{1/2}.$$

The first factor is directly controlled by $c\|f\|$ by assumption. For the second factor, write

$$(Q_t^B)^*g = (I + t^{2k}DB^*DB^*)^{-1}t^kDB^*g = t^kDB^*(I + t^{2k}DB^*DB^*)^{-1}g.$$

We shall show in a moment that quadratic estimates for operators DB^* are a consequence of the assumed quadratic estimates for B^*D . We conclude that $\text{sgn}(BD)$ is bounded as desired.

We remark that $\text{sgn}(BD)\text{sgn}(BD) = I$ on $\overline{R(BD)}$ from the properties of functional calculus. This gives the invertibility of $\text{sgn}(BD)$ on $\overline{R(BD)}$, and the proposition is proved.

6.2. Operators of type DB .

Proposition 6.1. *Under (H2,4,5), we have*

- (i) *The operator DB is ω -bisectorial, i.e. $\sigma(DB) \subset S_\omega$ and there are resolvent bounds $\|(\lambda I - DB)^{-1}\| \lesssim 1/\text{dist}(\lambda, S_\omega)$ when $\lambda \notin S_\omega$.*
- (ii) *The operator DB has range $R(DB) = R(D)$ and null space $N(DB)$ such that topologically (but in general non-orthogonally) one has*

$$\mathcal{H} = \overline{R(DB)} \oplus N(DB).$$

- (iii) *The restriction of DB to $\overline{R(DB)}$ is a closed and injective operator with dense range in $\overline{R(DB)}$, with estimates on spectrum and resolvents as in (i).*
- (iv) *If BD satisfies the quadratic estimate (1), for example if (H1-6) are all satisfied, then for all $g \in \mathcal{H}$,*

$$(21) \quad \left(\int_0^\infty \|t^k DB(I + t^{2k}DBDB)^{-1}g\|^2 \frac{dt}{t} \right)^{1/2} \lesssim \|g\|.$$

If B is strictly accretive on all $\mathcal{H}$, then $DB = B^{-1}(BD)B$, so DB and BD are similar operators. In this case, bisectoriality, resolvent bounds, quadratic estimates and boundedness of functional calculus carries over from immediately BD to DB .

However we are only assuming that B is strictly accretive on $R(D)$ as in (H5). Denote by B' the restricted operator $B' = B : \overline{R(D)} \rightarrow \overline{BR(D)} = \overline{R(BD)}$. By (H4,5) this is an isomorphism, and we have $DB = (B')^{-1}(BD)B'$ on $\overline{R(DB)}$. Thus we can transfer results about BD on $\overline{R(BD)}$ to results about DB on $\overline{R(DB)}$.

To extend the action of DB to all of $\mathcal{H}$, we use (ii). To check (ii), note that DB and B^*D are adjoint operators so that $\overline{R(DB)} = N(B^*D)^\perp$ and $N(DB) = R(B^*D)^\perp$ and the splitting follows from Proposition 3.1(ii) on taking orthogonal complements.

7. SPECTRAL DECOMPOSITION AND DEPENDENCE ON B

For this section, we specialise to the case of first order differential operators D , i.e. $k = 1$, and assume that B is a multiplication operator.

We continue to treat DB , though the following results are readily adapted to BD .

Proposition 7.1. *Suppose the hypotheses (H1-5) are satisfied with $k = 1$, and that B is multiplication by a function $B \in L^\infty(\mathbf{R}^n, \mathcal{L}(\mathbf{C}^m))$. Then the following hold.*

- (i) *The operator $\text{sgn}(DB)$ is bounded on $\mathcal{H}$.*
- (ii) *The operator DB has a spectral decomposition $\overline{R(D)} = \overline{R(DB)} = \mathcal{H}_{DB+} \oplus \mathcal{H}_{DB-}$ where $\mathcal{H}_{DB\pm} = \{v \in \overline{R(D)} : \text{sgn}(DB)v = \pm v\}$.*

- (iii) The projections of $\overline{R(D)}$ onto $\mathcal{H}_{DB\pm}$ are $E_{\pm}^B = 1/2(I \pm \operatorname{sgn}(DB))$.
- (iv) The restriction of DB to $\mathcal{H}_{DB+}$ is ω -sectorial and thus generates a bounded analytic semigroup e^{-tDB} in $\mathcal{H}_{DB+}$ which satisfies $\lim_{t \rightarrow \infty} e^{-tDB}v \rightarrow 0$ and $\lim_{t \rightarrow 0} e^{-tDB}v \rightarrow v$ for all $v \in \mathcal{H}_{DB+}$.

Indeed $V := e^{-tDB}v$ is the unique function in $C^1(\mathbf{R}_+, \mathcal{H})$ which satisfies $\frac{\partial}{\partial t}V(t) + DBV(t) = 0$ for $t > 0$, as well as the limiting conditions just mentioned.

Part (i) is proved in the same way as Proposition 1.3 once we have the quadratic estimates (1) and (21). The other parts follow as a consequence.

We remark that, by the preceding two propositions, there is a spectral decomposition

$$\mathcal{H} = \mathcal{H}_{DB+} \oplus \mathcal{H}_{DB-} \oplus \mathbf{N}(DB)$$

corresponding to the right and left sectors of S_{ω} and $\{0\}$.

It is an important consequence of proving bounds for a general class of matrices B , that all of the corresponding bounded operators such as $\operatorname{sgn}(DB)$ depend analytically on B . To prove this, start by showing analytic dependence for the resolvents, and then prove analyticity for more general operators by using the fact that uniform limits of analytic functions are analytic. See [8, 3] for further details. We need this fact for the projections $E_{\pm}^B$ defined above.

Proposition 7.2. *Suppose that $z \mapsto B_z$ is an analytic function from z in an open set $\Omega \subset \mathbf{C}$ to functions $B_z \in L^{\infty}(\mathbf{R}^n, \mathcal{L}(\mathbf{C}^m))$, and that the operators D and multiplication by B_z in $\mathcal{H}$ satisfy (H1-5) with $k = 1$ under uniform bounds. Then the projections $E_{\pm}^{B_z} : \overline{R(D)} \rightarrow \mathcal{H}_{DB_z\pm} \subset \overline{R(D)}$ depend analytically on B .*

8. ELLIPTIC SYSTEMS WITH SQUARE INTEGRABLE BOUNDARY DATA

Let us illustrate the power of our estimates by showing that elliptic systems on $\mathbf{R}_+^{1+n} = \{(t, x); t > 0\}$ of the form

$$(22) \quad \operatorname{div}_{t,x} A(x) \nabla_{t,x} F(t, x) = 0$$

are well-posed under L^2 Neumann data on $\mathbf{R}^n$, when the coefficient matrix A is self-adjoint, strictly accretive, and has coefficients which are bounded measurable functions of $x \in \mathbf{R}^n$. The functions F map $\mathbf{R}_+^{1+n}$ to $\mathbf{C}^N$. One can also handle L^2 Dirichlet and $\dot{H}^1$ Dirichlet data, thus generalising results concerning the case $N = 1$ and real symmetric coefficients [19, 15, 20]. See [3] for a more extensive theory and for the historical background.

8.1. Results. On writing

$$U(t, x) = \begin{bmatrix} U_0(t, x) \\ \mathbf{U}(t, x) \end{bmatrix} = \begin{bmatrix} \frac{\partial}{\partial t} F(t, x) \\ \nabla_x F(t, x) \end{bmatrix} = \nabla_{t,x} F(t, x)$$

where U takes values in $\mathbf{C}^N \oplus \mathbf{C}^{nN}$, the second order equation can be rewritten as a first order system

$$(23) \quad \operatorname{div}_{t,x} A(x) U(t, x) = 0 \quad \text{and}$$

$$(24) \quad \operatorname{curl}_{t,x} U(t, x) = 0$$

for $(t, x) \in \mathbf{R}_+^{n+1}$. We assume throughout this section that the coefficient matrix $A \in L^\infty(\mathbf{R}^n, \mathcal{L}(\mathbf{C}^N \oplus \mathbf{C}^{nN}))$ is strictly accretive in the sense that

$$\operatorname{Re} \left(A \begin{bmatrix} f \\ \nabla_x g \end{bmatrix}, \begin{bmatrix} f \\ \nabla_x g \end{bmatrix} \right) \geq \kappa (\|f\|^2 + \|\nabla_x g\|^2)$$

for some $\kappa > 0$ and all $f \in L^2(\mathbf{R}^n, \mathbf{C}^N)$, $g \in \dot{H}^1(\mathbf{R}^n, \mathbf{C}^N)$. For the moment we do not assume self-adjointness of A .

The *Neumann problem* for (22) is *well-posed in the $L^\infty(L^2)$ sense* means that, given $w \in L^2(\mathbf{R}^n, \mathbf{C}^N)$, there exists a unique function $U \in C^1(\mathbf{R}_+, L^2(\mathbf{R}^n, \mathbf{C}^N \oplus \mathbf{C}^{nN}))$ which satisfies (23) and (24) on $\mathbf{R}_+^{1+n}$, as well as $\lim_{t \rightarrow \infty} U(t, \cdot) = 0$ and $\lim_{t \rightarrow 0} U(t, \cdot) = u$ in the L^2 sense, where

$$(25) \quad (Au)_0 = \sum_{j=0}^n A_{0,j} u_j = w \quad \text{on } \mathbf{R}^n.$$

Our aim is to prove the following result.

Proposition 8.1. *Assume, in addition to the above conditions, that A is self-adjoint. Then the Neumann problem for (22) is well-posed in the $L^\infty(L^2)$ sense.*

In fact the solutions satisfy quadratic estimates and have non-tangential maximal function estimates. See [3] for this, and for a treatment of more general conditions on A and other boundary conditions.

8.2. A related equation. In what follows, we write

$$(26) \quad A = \begin{bmatrix} a & b \\ c & d \end{bmatrix},$$

where a, b, c, d are L^∞ functions taking values $a(x) \in \mathcal{L}(\mathbf{C}^N)$, $b(x) \in \mathcal{L}(\mathbf{C}^{nN}, \mathbf{C}^N)$, $c(x) \in \mathcal{L}(\mathbf{C}^N, \mathbf{C}^{nN})$, $d(x) \in \mathcal{L}(\mathbf{C}^{nN})$ for a.a. $x \in \mathbf{R}^n$. Also write

$$(27) \quad U = \begin{bmatrix} U_0 \\ \mathbf{U} \end{bmatrix}; \quad V = \begin{bmatrix} V_0 \\ \mathbf{V} \end{bmatrix} = \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix} U$$

where $U_0, V_0 : \mathbf{R}_+^{1+n} \rightarrow \mathbf{C}^N$ and $\mathbf{U}, \mathbf{V} : \mathbf{R}_+^{1+n} \rightarrow \mathbf{C}^{nN}$ and set

$$(28) \quad D = \begin{bmatrix} 0 & \operatorname{div} \\ -\nabla & 0 \end{bmatrix}$$

where $\nabla = \nabla_x$ and $\operatorname{div} = -\nabla^*$. This operator D satisfies (H1,2,3).

Note that $\overline{\mathbf{R}(D)} = L^2(\mathbf{R}^n, \mathbf{C}^N) \oplus \overline{\mathbf{R}(\nabla)}$. So the coercivity condition on A is really coercivity on $\overline{\mathbf{R}(D)}$, i.e.

$$\operatorname{Re}(ADu, Du) \geq \kappa \|Du\|^2$$

for all $u \in \mathbf{D}(D)$.

We note that this inequality implies the pointwise accretivity $\operatorname{Re}(a(x)\xi, \xi) \geq \kappa |\xi|^2$ for all $\xi \in \mathbf{C}^N$ so we may define

$$\hat{A} = \begin{bmatrix} 1 & 0 \\ c & d \end{bmatrix} \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix}^{-1}.$$

In the next subsection we show that $\hat{A}$ is also bounded and strictly accretive on $\overline{\mathbf{R}(D)}$.

Proposition 8.2. *A function $U \in C^1(\mathbf{R}_+, L^2(\mathbf{R}^n, \mathbf{C}^N \oplus \mathbf{C}^{nN}))$ satisfies (23) and (24) on $\mathbf{R}_+^{1+n}$ if and only if the function $V \in C^1(\mathbf{R}_+, L^2(\mathbf{R}^n, \mathbf{C}^N \oplus \mathbf{C}^{nN}))$ satisfies*

$$(29) \quad \frac{\partial}{\partial t} V + D\hat{A}V = 0 \quad \text{and}$$

$$(30) \quad \operatorname{curl}_x \mathbf{V}(t, \cdot) = 0$$

on $\mathbf{R}_+^{1+n}$.

Proof. Equation (29), namely

$$\frac{\partial}{\partial t} \begin{bmatrix} V_0 \\ \mathbf{V} \end{bmatrix} + \begin{bmatrix} 0 & \operatorname{div} \\ -\nabla & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ c & d \end{bmatrix} \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix}^{-1} \begin{bmatrix} V_0 \\ \mathbf{V} \end{bmatrix} = 0 ,$$

is equivalent to

$$\frac{\partial}{\partial t} \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix} \begin{bmatrix} U_0 \\ \mathbf{U} \end{bmatrix} + \begin{bmatrix} 0 & \operatorname{div} \\ -\nabla & 0 \end{bmatrix} \begin{bmatrix} 1 & 0 \\ c & d \end{bmatrix} \begin{bmatrix} U_0 \\ \mathbf{U} \end{bmatrix} = 0 ,$$

which is in turn equivalent to the pair of equations

$$\begin{aligned} \left[\frac{\partial}{\partial t} \quad \operatorname{div} \right] \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} U_0 \\ \mathbf{U} \end{bmatrix} &= 0 \\ \frac{\partial}{\partial t} \mathbf{U} - \nabla U_0 &= 0 . \end{aligned}$$

The first of these is (23), while the second, when taken together with (30), is (24). $\square$

The Neumann condition (25) becomes $V_0 = w$ on $\mathbf{R}^n$.

8.3. The map $A \mapsto \hat{A}$. Let us look at the correspondence between a bounded strictly accretive matrix $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ and $\hat{A} = \begin{bmatrix} 1 & 0 \\ c & d \end{bmatrix} \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix}^{-1}$. As observed before, the sub-matrix a is itself bounded, strictly accretive on $L^2(\mathbf{R}^n, \mathbf{C}^N)$, and the inverse $\begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix}^{-1}$ exists and is bounded. For interest, we note that $\hat{\hat{A}} = A$.

Proposition 8.3. *Given a bounded matrix A as above which is strictly accretive on $\overline{R(D)}$, then $\hat{A}$ is also bounded, strictly accretive on $\overline{R(D)}$.*

Proof. This is easily verified, once we have the following identity:

$$\begin{aligned} \operatorname{Re} \left(\hat{A} \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix} \begin{bmatrix} u_0 \\ \mathbf{u} \end{bmatrix}, \begin{bmatrix} a & b \\ 0 & 1 \end{bmatrix} \begin{bmatrix} u_0 \\ \mathbf{u} \end{bmatrix} \right) &= \operatorname{Re}((u_0, au_0 + b\mathbf{u}) + (cu_0 + d\mathbf{u}, \mathbf{u})) \\ &= \operatorname{Re}((au_0 + b\mathbf{u}, u_0) + (cu_0 + d\mathbf{u}, \mathbf{u})) \\ &= \operatorname{Re} \left(A \begin{bmatrix} u_0 \\ \mathbf{u} \end{bmatrix}, \begin{bmatrix} u_0 \\ \mathbf{u} \end{bmatrix} \right) . \end{aligned}$$

$\square$

Self-adjointness is not preserved under this transformation. Indeed, it can readily be checked that A is self-adjoint if and only if $\hat{A}$ has the form $\hat{A} = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix}$ with $\alpha = \alpha^*$, $\beta = -\gamma^*$ and $\delta = \delta^*$.

8.4. Results for $D\hat{A}$. We now apply the theory which we have developed concerning operators of the form DB to the present situation. So take $\mathcal{H} = L^2(\mathbf{R}^n, \mathbf{C}^N \oplus \mathbf{C}^{nN})$, $B = \hat{A}$ and

$$D = \begin{bmatrix} 0 & \text{div} \\ -\nabla & 0 \end{bmatrix}.$$

The pair $(D, \hat{A})$ satisfies (H1-5) and $\hat{A}$ is a multiplication operator. Therefore, by Proposition 7.1, the spectral projection $E_+^{\hat{A}} : \overline{\mathcal{R}(D)} \rightarrow \mathcal{H}_{D\hat{A}+}$ is bounded.

The functions $v \in \mathcal{H}_{D\hat{A}+}$ are precisely the boundary values of functions V on $\mathbf{R}_+^{1+n}$ which satisfy (29) and (30). Moreover $V(t) = e^{-tD\hat{A}}v$ for $t > 0$. And the Neumann problem for (22) is the determination of v , and hence V , from its first component, $v_0 = w$, where $w \in L^2(\mathbf{R}^n, \mathbf{C}^N)$ is given. We are writing $v = \begin{bmatrix} v_0 \\ \mathbf{v} \end{bmatrix}$. So, on defining the operator $P_{\hat{A}} : \mathcal{H}_{D\hat{A}+} \rightarrow L^2(\mathbf{R}^n, \mathbf{C}^N)$ by $P_{\hat{A}}v = v_0$, we have the following result.

Proposition 8.4. *The Neumann problem (22) is well posed in the $L^\infty(L^2)$ sense if and only if $P_{\hat{A}} : \mathcal{H}_{D\hat{A}+} \rightarrow L^2(\mathbf{R}^n, \mathbf{C}^N)$ has a bounded inverse.*

This means that, given $w \in L^2(\mathbf{R}^n, \mathbf{C}^N)$, there exists a unique function $v \in \mathcal{H}_{D\hat{A}+}$ with $v_0 = w$, and hence there exists a unique function $V \in C^1(\mathbf{R}_+, L^2(\mathbf{R}^n, \mathbf{C}^N \oplus \mathbf{C}^{nN}))$ which satisfies $\frac{\partial}{\partial t}V + D\hat{A}V = 0$, $\lim_{t \rightarrow \infty} V(t) = 0$, $\lim_{t \rightarrow 0} V(t) = v$.

Now the Neumann problem is not always well-posed [21], and $P_{\hat{A}}$ is not always an isomorphism.

Our aim though is to prove Proposition 8.1, or in other words, to show that when A is self-adjoint, then $P_{\hat{A}}$ is an isomorphism.

8.5. Unperturbed operators. In order to tie our results in with the classical theory, we start with $A = \hat{A} = I$. In this case $v = \begin{bmatrix} v_0 \\ \mathbf{v} \end{bmatrix} \in \mathcal{H}_{D+}$ if and only if $\text{curl } \mathbf{v} = 0$ and $Dv = \sqrt{(D^2)}v$, i.e.

$$\begin{bmatrix} 0 & \text{div} \\ -\nabla & 0 \end{bmatrix} \begin{bmatrix} v_0 \\ \mathbf{v} \end{bmatrix} = \begin{bmatrix} \sqrt{-\Delta} & 0 \\ 0 & \sqrt{-\nabla \text{div}} \end{bmatrix} \begin{bmatrix} v_0 \\ \mathbf{v} \end{bmatrix}$$

where $\Delta = \text{div} \nabla$ is the Laplacian on $\mathbf{R}^n$. That is, $\mathbf{v} = -\nabla(-\Delta)^{-1/2}v_0$, or equivalently, $v_0 = (-\Delta)^{-1/2} \text{div } \mathbf{v}$ and $\text{curl } \mathbf{v} = 0$.

Thus the map P_I is an isomorphism, and so, as we know, the Neumann problem for the Laplacian on the upper half space is well posed in the $L^\infty(L^2)$ sense.

8.6. Rellich inequality. We now consider bounded, strictly accretive, self-adjoint matrices A . In this case $\hat{A}$ has the form $\hat{A} = \begin{bmatrix} \alpha & \beta \\ \gamma & \delta \end{bmatrix}$ with $\alpha = \alpha^*$, $\beta = -\gamma^*$ and $\delta = \delta^*$, or in other words, $(\hat{A})^*K = K\hat{A}$ where $K = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}$.

Since $KD + DK = 0$, we have, for $v \in \mathcal{H}_{D\hat{A}+}$ and $V = e^{-tD\hat{A}}v$, that

$$(K\hat{A}v, v) = - \int_0^\infty (K \frac{\partial}{\partial t}V, \hat{A}V) + (K\hat{A}V, \frac{\partial}{\partial t}V) = \int_0^\infty (KD\hat{A}V, \hat{A}V) + (DK\hat{A}V, \hat{A}V) = 0$$

or in other words,

$$(\alpha v_0, v_0) + 2 \text{Re}(\beta \mathbf{v}, v_0) - (\delta \mathbf{v}, \mathbf{v}) = 0.$$

Therefore, as $\mathbf{v} \in \overline{\mathbf{R}(\nabla)}$ and δ is strictly accretive on $\overline{\mathbf{R}(\nabla)}$, we have

$$\|\mathbf{v}\|^2 \lesssim \operatorname{Re}(\delta \mathbf{v}, \mathbf{v}) \lesssim \|v_0\|^2 + \|\mathbf{v}\| \|v_0\|$$

and hence the Rellich inequality

$$\|\mathbf{v}\| \lesssim \|v_0\|$$

for all $v \in \mathcal{H}_{D\hat{A}+}$. This in turn tells us that the mapping $P_{\hat{A}} : v \rightarrow v_0$ satisfies the *a priori* estimates $\|P_{\hat{A}}v\| \approx \|v\|$ for all $v \in \mathcal{H}_{D\hat{A}+}$.

To prove surjectivity of $P_{\hat{A}}$, use the method of continuity (i.e. the invariance of semi-Fredholm index) for the family $B_\tau = \tau \hat{A} + (I - \tau)I$, $0 \leq \tau \leq 1$, and the fact that P_I is an isomorphism. For this we need to know that the spaces $\mathcal{H}_{DB_\tau+}$, or in other words the projections $E_+^{B_\tau}$, depend continuously on τ .

In fact B_τ depends analytically on $\tau \in \mathbf{C}$. Moreover, on some open subset $\Omega \subset \mathbf{C}$ which contains the closed real interval $[0, 1]$, the operators D, B_τ satisfy (H1-5) with uniform bounds. Therefore, by Proposition 7.2, the projections $E_+^{B_\tau}$ are actually analytic in τ .

This completes the proof of Proposition 8.1.

Remark 8.5. The results on analytic dependence imply even more, namely that the Neumann problem is well-posed in the $L^\infty(L^2)$ sense for all coefficient matrices A which are sufficiently small perturbations of a self-adjoint matrix. See [3].

Our aim has been to show that the functional calculus provides a mechanism to turn a Rellich estimate (i.e., comparability in the L^2 norm of transverse and tangential derivatives, which always holds for self-adjoint, t -independent, divergence form elliptic operators) into L^2 solvability. Previously, such a mechanism had existed in the case of a single equation with real symmetric coefficients (e.g., as in [19, 20]), or in the case of a block diagonal matrix (i.e., the setting of the Kato problem, in which case the square function estimates are equivalent to a Rellich estimate), or in the case of a system with constant coefficients.

9. INHOMOGENEOUS D WHEN $k = 1$

Consider operators D and B on $\mathcal{H} = L^2(\mathbf{R}^n, \mathbf{C}^m)$ with the requirement (inhH) which consists of (inhH1): The operator $D : \mathbf{D}(D) \rightarrow \mathcal{H}$ is a (inhomogeneous) first order differential operator with constant coefficients, (H2), (inhH3):

$$\|u\| + \|\nabla u\| \lesssim \|Du\|, \quad \text{for all } u \in \mathbf{D}(D) \cap \overline{\mathbf{R}(D)},$$

(H4,5) and B is a multiplication by a matrix-valued function.

Then we claim that the conclusion of the main theorem is valid replacing (H) by (inhH). The proof consists in going back to the homogeneous case (It would be nice to have a direct proof as in Section 3).

Write $D = D_1 + D_0$ where D_1 is a homogeneous first order differential operator and D_0 is multiplication by a constant matrix. We observe that since D is self-adjoint, so are D_0 and D_1 as seen by computing the Fourier symbols. Also, using Fourier arguments again, one can check that (H3) holds for D_1 . So one can define $(I + itBD_1)^{-1}$, the corresponding Q_t^1 , and obtain the conclusion of Theorem 1.1 for Q_t^1 . Observe that

$$\|(I + itBD)^{-1} - (I + itBD_1)^{-1}\| = \|(I + itBD)^{-1}(tBD_0)(I + itBD_1)^{-1}\| \lesssim |t|.$$

Recall that $Q_t^B = \frac{1}{2i}(R_{-t}^B - R_t^B)$, hence

$$\|tBD(I + t^2BDBD)^{-1} - tBD_1(I + t^2BD_1BD_1)^{-1}\| \lesssim t.$$

So $\int_0^1 \|\Theta_t u\|^2 \frac{dt}{t} \lesssim \|u\|^2$ for all $u \in \mathcal{H}$ follows from (1) for BD_1 .

It remains to control $\int_1^\infty \|\Theta_t u\|^2 \frac{dt}{t}$ and we know that it suffices to assume $u = Dv$ with $v \in \mathcal{D}(D)$. We can also assume $v \in \overline{\mathcal{R}(D)}$ from (4). But $\|\Theta_t D\| \lesssim t^{-1}$, hence $\int_1^\infty \|\Theta_t Dv\|^2 \frac{dt}{t} \lesssim \|v\|^2$ and we conclude invoking (inhH3).

For the application to the Kato problem for second order elliptic operators with lower order terms $L = -\operatorname{div} A \nabla + \operatorname{div} b - c \nabla + d$, where A, b, c, d are multiplication operators with $L^\infty(\mathbf{R}^n, \mathbf{C})$ coefficients and $\begin{bmatrix} A & b \\ c & d \end{bmatrix}$ is strictly accretive on $L^2(\mathbf{R}^n, \mathbf{C}^{n+1})$, we take

$$(31) \quad D := \begin{bmatrix} 0 & \operatorname{div}_x & 1 \\ -\nabla_x & 0 & 0 \\ 1 & 0 & 0 \end{bmatrix}, \quad B := \begin{bmatrix} 1 & 0 & 0 \\ 0 & A & b \\ 0 & c & d \end{bmatrix}.$$

Remark 9.1. The inhomogenous version for higher order D is in [6, Section 0.7]. Further results on inhomogeneous problems are in [9].

10. RELATED OPERATORS AND FURTHER APPLICATIONS

The aim of this section is to see that operators BD or DB are the building blocks of other operators obtained by functional analytic considerations in such a way that results for DB and BD apply immediately. We will finish with a concrete application to the functional calculus of Dirac type operators on forms.

10.1. Operators of type $\Gamma + B^{-1}\Gamma^*B$. This class of perturbed Dirac operators was studied in [8], where bisectoriality and quadratic estimates were proved. As a corollary, our Theorem 1.1 was proved in [8, Theorem 3.1(iii)]. In this section we prove the converse to this, i.e. we deduce the results in [8] from Theorem 1.1.

As in [8], we consider the following slightly more general situation. Let Γ and Γ^* be adjoint nilpotent operators in an arbitrary Hilbert space $\mathcal{H}$, i.e. $\Gamma^2 = (\Gamma^*)^2 = 0$, let B_1, B_2 be bounded operators such that B_1 is strictly accretive on $\mathcal{R}(\Gamma^*)$ and B_2 is strictly accretive on $\mathcal{R}(\Gamma)$. Furthermore, assume that $\Gamma^*B_2B_1\Gamma^* = 0$ and $\Gamma B_1B_2\Gamma = 0$. This holds in particular if $(B_1, B_2) = (B^{-1}, B)$ with B strictly accretive on all of $\mathcal{H}$. For more details on this hypothesis, we refer to (H1-3) in [8]. In this case, the operator on $\mathcal{H}$

$$\Pi_B := \Gamma + \Gamma_B^*, \quad \Gamma_B^* := B_1\Gamma^*B_2$$

induces a Hodge type splitting

$$(32) \quad \mathcal{H} = (\mathcal{N}(\Gamma_B^*) \cap \mathcal{N}(\Gamma)) \oplus \overline{\mathcal{R}(\Gamma_B^*)} \oplus \overline{\mathcal{R}(\Gamma)}.$$

Now consider the operators

$$D := \begin{bmatrix} 0 & \Gamma^* \\ \Gamma & 0 \end{bmatrix}, \quad B := \begin{bmatrix} B_1 & 0 \\ 0 & B_2 \end{bmatrix}$$

acting in $\mathcal{H} \oplus \mathcal{H}$. Note that the hypothesis on $\Gamma, \Gamma^*, B_1, B_2$ above is equivalent with (H2,4,5) for D, B . Using the fact that the Hodge splitting (32) is topological, the map

$$S : \mathcal{H} \longrightarrow \mathcal{H} \oplus \mathcal{H} : f_0 + f_1 + f_2 \longmapsto \begin{bmatrix} f_1 \\ B_2 f_2 \end{bmatrix}$$

is well-defined and bounded, and one can show that the restriction of S to $\overline{\mathbf{R}(\Pi_B)} = \overline{\mathbf{R}(\Gamma_B^*)} \oplus \overline{\mathbf{R}(\Gamma)}$ is an isomorphism onto $\overline{\mathbf{R}(BD)}$. Since

$$\begin{aligned} BDS(0 + f_1 + f_2) &= \begin{bmatrix} 0 & B_1\Gamma^* \\ B_2\Gamma & 0 \end{bmatrix} \begin{bmatrix} f_1 \\ B_2f_2 \end{bmatrix} = \begin{bmatrix} \Gamma_B^*f_2 \\ B_2(\Gamma f_1) \end{bmatrix} \\ &= S(0 + \Gamma_B^*f_2 + \Gamma f_1) = S(\Pi_B(0 + f_1 + f_2)), \end{aligned}$$

we have shown that the restrictions $BD : \overline{\mathbf{R}(BD)} \rightarrow \overline{\mathbf{R}(BD)}$ and $\Pi_B : \overline{\mathbf{R}(\Pi_B)} \rightarrow \overline{\mathbf{R}(\Pi_B)}$ are similar operators. Consequently, we obtain the following.

Proposition 10.1. *Let Π_B in $\mathcal{H}$ and BD in $\mathcal{H} \oplus \mathcal{H}$ be as above. Π_B is a bisectorial operator on $\mathcal{H}$ with resolvent bounds. Furthermore, if BD satisfies quadratic estimates, so does Π_B .*

10.2. Operators of type $BD_1 + D_2B^{-1}$. In this section we aim to deduce quadratic estimates for operators well adapted to boundary value problems for differential forms. Similar to our discussion of the class of operators Π_B above, we consider the following slightly more general class of operators

$$B_1D_1 + D_2B_2$$

acting in an arbitrary Hilbert space $\mathcal{H}$. We assume that the two pairs of operators (D_1, B_1) and (D_2, B_2) both satisfy (H2,4,5), and the following compatibility conditions. For the unperturbed operators D_1 and D_2 , we assume that $\mathbf{R}(D_1) \subset \mathbf{N}(D_2)$ and $\mathbf{R}(D_2) \subset \mathbf{N}(D_1)$. This means in particular that $D_2D_1 = 0 = D_1D_2$ on appropriate domains. For the perturbed operators we assume that $B_2B_1 : \mathbf{R}(D_1) \rightarrow \mathbf{N}(D_2)$ so that $D_2B_2B_1D_1 = 0$ on $\mathbf{D}(D_1)$. This holds in particular if $(B_1, B_2) = (B, B^{-1})$ with B strictly accretive on all of $\mathcal{H}$.

Similar to the fact that an operator Π_B acts by swapping the two ranges in its Hodge splitting, an operator $B_1D_1 + D_2B_2$ acts diagonally in the associated splitting

$$(33) \quad \mathcal{H} = \left(\mathbf{N}(B_1D_1) \cap \mathbf{N}(D_2B_2) \right) \oplus \overline{\mathbf{R}(B_1D_1)} \oplus \overline{\mathbf{R}(D_2B_2)}$$

of $\mathcal{H}$. To see this splitting, note that

$$\mathcal{H} = \overline{\mathbf{R}(B_1D_1)} \oplus \mathbf{N}(B_1D_1) = \mathbf{N}(D_2B_2) \oplus \overline{\mathbf{R}(D_2B_2)},$$

and (33) follows by intersecting these two splittings since $\mathbf{R}(B_1D_1) \subset \mathbf{N}(D_2B_2)$ and $\mathbf{R}(D_2B_2) \subset \mathbf{N}(B_1D_1)$. Since B_1D_1 and D_2B_2 act as

$$B_1D_1 = 0 \oplus B_1D_1 \oplus 0, \quad D_2B_2 = 0 \oplus 0 \oplus D_2B_2$$

in the splitting (33), the operator $B_1D_1 + D_2B_2$ is the direct sum of these two operators, namely

$$B_1D_1 + D_2B_2 : \mathcal{H} \longrightarrow \mathcal{H} : f_0 + f_1 + f_2 \longmapsto 0 + B_1D_1f_1 + D_2B_2f_2.$$

This shows the following.

Proposition 10.2. *Assume that D_1, B_1 and D_2, B_2 are as above. Then $B_1D_1 + D_2B_2$ is a bisectorial operator on $\mathcal{H}$ with resolvent bounds. Furthermore, if B_1D_1 and D_2B_2 satisfy quadratic estimates, then so does $B_1D_1 + D_2B_2$.*

10.3. An application to Dirac type equations. We end with an application of the quadratic estimates for the class of operators $B_1 D_1 + D_2 B_2$ to boundary value problems for differential forms. The goal is to prove that the underlying operator T_B used in [2] to obtain perturbation results for BVPs for Dirac type equations, and in particular for BVPs for second order divergence form equations, has quadratic estimates for **all** complex strictly accretive coefficients B . In [2], quadratic estimates were proved only for special types of coefficients B , namely for small perturbations of real symmetric, constant and block form coefficients.

The operators T_B are infinitesimal generators for the studied Dirac equations, and following [2, Definition 2.10] we have

$$T_B = -iM_B^{-1}(\underline{d} + B^{-1}\underline{d}^*B),$$

which acts in $L^2(\mathbf{R}^n; \wedge)$, where $\wedge = \wedge_{\mathbf{C}} \mathbf{R}^{1+n}$ is the full complexified exterior algebra of $\mathbf{R}^{1+n}$. Here $\underline{d}$ is a nilpotent differential operator, i.e. $\underline{d}^2 = 0$, and B is a strictly accretive multiplication operator so that the operator T_B , modulo the factor $-iM_B$ (being an invertible, non-accretive, multiplication operator), is of type Π_B . More precisely, if $\mu f = e_0 \wedge f$ is exterior multiplication by the basis vector normal to $\mathbf{R}^n$ and $m := \mu + \mu^*$ then $\underline{d} := imd$ where d is the exterior derivative, and $M_B := \mu^* \mu - B^{-1} \mu \mu^* B$. In the work [2], this factor complicated the application of results for the class Π_B and only gave partial results. However, in connection with the later work [3], it was realized that the operators T_B actually are similar to operators of type $B_1 D_1 + D_2 B_2$. This similarity uses the transform $B \mapsto \hat{B} := \underline{B} \overline{B}^{-1}$ of strictly accretive matrices analogous to Proposition 8.3, on splitting the space $L^2(\mathbf{R}^n; \wedge)$ into normal and tangential forms and writing the operators $B, \underline{B}, \overline{B}$ as the matrices

$$B = \begin{bmatrix} B_{\perp\perp} & B_{\perp\parallel} \\ B_{\parallel\perp} & B_{\parallel\parallel} \end{bmatrix}, \quad \underline{B} = \begin{bmatrix} I & 0 \\ B_{\parallel\perp} & B_{\parallel\parallel} \end{bmatrix}, \quad \overline{B} = \begin{bmatrix} B_{\perp\perp} & B_{\perp\parallel} \\ 0 & I \end{bmatrix}.$$

This is summarized in the following new result.

Corollary 10.3. *Let $B \in L^\infty(\mathbf{R}^n; \mathcal{L}(\wedge))$ be any complex coefficient matrix function which is strictly accretive on $L^2(\mathbf{R}^n, \wedge)$, matrix function. Then*

$$T_B = \overline{B}^{-1} \left(D_1 \hat{B} + \hat{B}^{-1} D_2 \right) \overline{B},$$

where the differential operators are $D_1 := \mu^* d - \mu d^*$ and $D_2 := \mu^* d^* - \mu d$. In particular T_B is an injective ω -bisectorial operator, ω being the angle of accretivity of $\hat{B}$, has resolvent bounds and satisfies quadratic estimates in $L^2(\mathbf{R}^n; \wedge)$.

Proof. Since D_1, D_2 are first order differential operators, according to Theorem 1.1, Proposition 10.2 and Proposition 5.1, it suffices to verify the similarity. Multiplying the equation with BM_B , it suffices to show that

$$-i(B\underline{d} + \underline{d}^*B) = (BM_B)(\overline{B}^{-1}D_1\underline{B} + \underline{B}^{-1}D_2\overline{B}).$$

Identifying $e_0 \wedge f_1 + f_2 \in L^2(\mathbf{R}^n; \wedge \mathbf{R}^{1+n})$ with $[f_1, f_2]^t \in L^2(\mathbf{R}^n; \wedge \mathbf{R}^n)^2$, the above definitions give $-i\underline{d} = \begin{bmatrix} 0 & d \\ -d & 0 \end{bmatrix}$, $-i\underline{d}^* = \begin{bmatrix} 0 & d^* \\ -d^* & 0 \end{bmatrix}$, $BM_B = \begin{bmatrix} -B_{\perp\perp} & 0 \\ 0 & B_{\parallel\parallel} \end{bmatrix}$, $D_1 = -\begin{bmatrix} 0 & d^* \\ d & 0 \end{bmatrix}$ and $D_2 = -\begin{bmatrix} 0 & d \\ d^* & 0 \end{bmatrix}$. The similarity is now straightforward to verify. $\square$

We end with the remark that it is only the part $\hat{T}_B$ similar to $D_1\hat{B}$ of the full operator T_B that is needed for the application to boundary value problems for k -vector fields / k -forms. This application is described in [3, Section 6]. The complementary part $\tilde{T}_B$ similar to $\hat{B}^{-1}D_2$ will mix k -vector fields of different order k , but has the advantage of making the full operator T_B injective.
